

# Chapter 1

# TBM File Format

### 1.1 Introduction

The Ampex TMS-4 Terabit Memory System ("TBM") was a tape storage system used at NCAR from approximately the mid 1970s through to the mid 1980s. Much of the GENPRO-I data from this time period on HPSS was formerly only available in TBM-formatted archives. This document describes the format of these archives, as well as the TBMconv software framework which may be used to extract the contents of TBM files.

#### 1.2 TBM Format Overview

A TBM file begins with a SYSLBN block (see section 3.3) at offset 0. This block contains information such as:

- the machine used to generate the TBM file (e.g., the Cray 1),
- the data type (e.g., CDC DPC),
- the size of a "BK block," and
- offsets to specific locations in the file.

Of particular interest are the "BK block" size (expressed in multiples of 2048 60-bit words), the data type, and the offsets. Bits 59-30 of word 29 ("offset to first file control pointer"; firstFCPOff in the API) of this SYSLBN block specify the offset, in 60-bit words, from the start of the file (offset 0) to the first file control pointer (see section 3.4). Each file control pointer is followed by a set of file history words (see section 3.5) and a set of block control pointers (see section 3.6). Each block control pointer is one 60-bit word in length, and there are a total of numbkblocks of them.

For a TBM archive containing only one file, one should find that

```
\begin{array}{ll} {\tt numBKBlocks} = & \underbrace{{\tt nextFCPOff}}_{{\tt From first file}} - ({\tt firstFCPOff} + 9) \\ & {\tt control pointer} \\ & {\tt located at} \\ & {\tt firstFCPOff} \end{array}
```

The length of the file is indicated by the values of numBKBlocks and bk in SYSLBN. The length of the file should be:

$$\text{file length}_{\text{8-bit bytes}} = \frac{(\text{numBKBlocks} + 1) \times \text{bk} \times 2048_{\text{60-bit words}} \times 60_{\text{bits per word}}}{8_{\text{bits per byte}}}.$$

The portions of a TBM file where actual data resides are broken into many data records; each data record is preceded by a data buffer flags (see section 3.7) word, also known as a "record control word." Each data buffer flag contains an offset (relative to it) specifying the location of the next data buffer flag (nextPtrOffset in the DataBufferFlags struct).

File data (including metadata) begins at one TLIB/BK block into the file and ends with a Data Buffer Flag whose isEOD property is set to 1; padding follows afterwards as needed to make the total file size an integer multiple of TLIB/BK blocks long. Files are bookended by metadata consisting of alternating Data Buffer Flags and VOL1/HDR1/HDR2 metadata

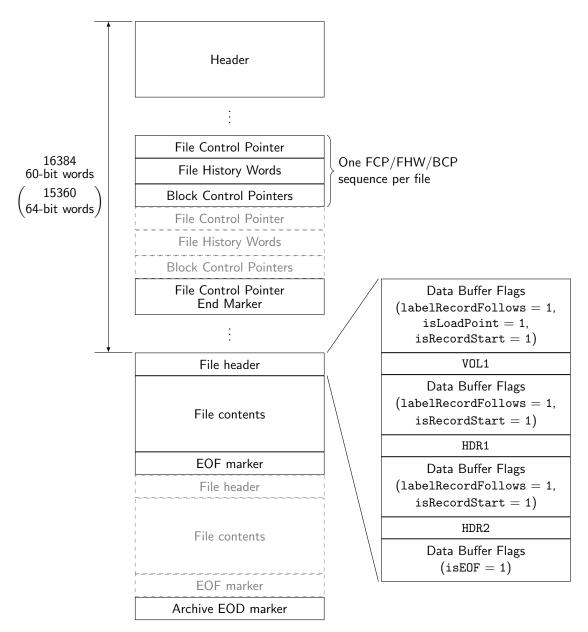

Figure 1.1: Illustration of the general TBM file layout.

at the beginning of each file and a DataBufferFlags structure at the end. The length of a TLIB block in terms of 60-bit words is

total TBM file length<sub>60-bit words</sub> = 
$$2048 \times bk$$
,

or in terms of 64-bit words,

total TBM file length 
$$_{\text{64-bit words}} = \frac{2048 \times \text{bk} \times 60}{64}.$$

For example, for the default bk value of 8,

$$\begin{split} \mathsf{length_{60\text{-}bit\ words}} &= 2048 \times 8 = 16384\ \mathsf{60\text{-}bit\ words}, \\ \mathsf{length_{64\text{-}bit\ words}} &= \frac{2048 \times 8 \times 60}{64} = 15360\ \mathsf{64\text{-}bit\ words}. \end{split}$$

A schematic diagram illustrating the most important elements of the TBM format is shown in Figure 1.1. An example from an actual file (NCAR/EOL dataset PHOENIX-78 file G50233) of offsets to data structures and some of their values illustrating the format is shown in Section 1.2.

## 1.2.1 Minimum Requirements for Reading a TBM Archive

For a TBM archive containing only one file, the only information from the first TLIB/BK block (containing the SYSLBN data structure as well as the file control pointers, file history words, and buffer control pointers) that is strictly necessary for reading a TBM archive is the "BK block" size (specified in the bk element of the SYSLBN\_Data structure in the API). With this information, the file contents can be extracted by stripping data buffer flags from the second TLIB/BK block through to the end of the file (denoted by a data buffer flags word with isE0D set to 1).

For a TBM archive containing multiple files, the same is sufficient, except that one must make note of the start and end of separate files within the archive, denoted by special data buffer flag / VOL1 / HDR1 / HDR2 sequences described previously.

# Chapter 2

# Using tbmexplore

tbmexplore is a command-line utility for interactively exploring/investigating the contents TBM files. tbmexplore permits dumping contents of a TBM file at arbitrary offsets, optionally decoding the

```
$ tbmexplore G51452
Enter an offset:
```

We enter 0 and press enter, and are next prompted with:

```
How would you like to display the data?

1) 6-bit DPC
2) Data Buffer Flags (aka ''Record Control Word")
3) Block Control Pointer
4) File Control Pointer
5) File History Word
6) SYSLBN
7) NotQuiteSYSLBN
8) VOL1
9) HDR1
10) HDR2
11) 20-bit integers
12) 60-bit integers
Enter a choice [1-12]:
```

#### Choosing 6, we see

# Chapter 3

# TBM Format and API Reference

### 3.1 API Introduction

tbmconv includes a header file (tbm.hpp) containing data structures useful for reading TBM files, as well as a set of routines for printing the contents of these structures to the terminal (contained in tbm.cpp). These data structures map to structures specified in the reference as illustrated in table 3.1.

Table 3.1

Data structure	API data str Raw data	cture names DPC	
SYSLBN	SYSLBN_Data	SYSLBN_Text	
VOL1	VOL1_Data	VOL1_Text	
HDR1	HDR1_Data	HDR1_Text	
HDR2	HDR2_Data	HDR2_Text	

The functions provided in tbm.cpp are:

```
void read_syslbn(uint8_t const*const inBuf, SYSLBN_Text *const text,
                 SYSLBN_Data *const data, const size_t offset);
void read_fileHistoryWord(uint8_t const*const inBuf,
                          FileHistoryWord_Text *const text,
                          FileHistoryWord_Data *const data,
                          const size_t offset);
void read_dataBufferFlags(uint8_t const*const inBuf,
                          DataBufferFlags *const dbf,
                          const size_t offset);
void read_fileControlPointer(uint8_t const*const inBuf,
                             FileControlPointer *const fcp,
                             const size_t offset);
void read_vol1(uint8_t const*const inBuf,
               VOL1_Text *const text,
               VOL1_Data *const data,
               const size_t offset);
void read_hdr1(uint8_t const*const inBuf,
               HDR1_Text *const text,
               HDR1_Data *const data,
               const size_t offset);
void read_hdr2(uint8_t const*const inBuf,
               HDR2_Text *const text ,
               HDR2_Data *const data,
               const size_t offset);
void print_vol1(VOL1_Text const*const text, VOL1_Data const*const data,
                const size_t offset);
void print_hdr1(HDR1_Text const*const text, HDR1_Data const*const data,
                const size_t offset);
void print_hdr2(HDR2_Text const*const text, HDR2_Data const*const data,
                const size_t offset);
```

## 3.2 Accessibility critera

The accessability critera characters are a character which indicate "any restrictions on who may have access to the information in this file. A space means unlimited access; any other character means special handling, in a manner to be defined."

### 3.3 SYSLBN

A SYSLBN block appears at the start of every TBM file, at offset 0. The SYSLBN block could be thought of as being comprised of a header (words 0 through 3), a VOL1 label (words 4–11), a HDR1 label (words 12–19), a HDR2 label (words 20–27), and finally pointers to various locations in the file (words 28–30).

18	47-30	DPC	${\tt creationDay}$	Creation day
12	29-18	DPC	${\tt expirationYear}$	Expiration year
18	17–0	DPC	expirationDay	Expiration day

### 3.5.8 File History Word 8

## 3.6 Block Control Pointer (BCP)

Sets of Block Control Pointers follow each set of File History Words, which in turn follow each File Control Pointer.

59	58 57		44 43 42 41 40 39 38 37 36 35 34 33 32 31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16 15 11 13 12 11 10 9 8 7 6 5 4 3 2 1 0
Rec Start	Ö	Checksum	Last record in data block N	Words to first pointer in data block N
Ž		 		, , , , , , , , , , , , , , , , , , ,

Length	Bits	Туре	API	Description
1	59	Binary	noRecordStartsHere	If set, no record starts in this block.
2	58–57	_	_	Open
12	56-45	Binary	checksum	Checksum <sup>1</sup>
21	44-24	Binary	lastRecord	Last record starting in data block N
24	23-0	Binary	wordsToFirstPtr	Words to first pointer in data block N

#### 3.6.1 Further Remarks

#### Representation in NCAR Technical Note

Note that the way the block control pointer is depicted in the NCAR Technical Note is rather confusing; the technical note shows what at first appear to be three distinct "block control pointers," one which is "word 9", another which is word "+9+M-1", and another which is word "+9+M". Really what the technical note is trying to convey is that there are M block control pointers per file; the first block control pointer starts at an offset +9 after the first file control pointer; and immediately after the last block control pointer (+9+M) is another file control pointer. If there are multiple files in a TBM archive, there will be multiple sets of block control pointers.

#### The lastRecord field

lastRecord is the one-based index of the last record to appear in the bk  $\times 2048$ -sized data block corresponding to a given buffer control pointer. For example, using tbmexplore to view the first three buffer control pointers shows that the "last record in data block N" for these are 35, 72, and 108.

<sup>&</sup>lt;sup>1</sup>Not mentioned in the NCAR Tech Note, but can be seen referenced on line 96 of the as.s CAL source file for tbm2cos.

	1	starts here		checksum	data	block N	1	words to first pointe in data block N
60	1	0	1	3496		35		22
61		0		2517		72		36
62		0	1	2696		108		52

Using tbmexplore to dump the offsets of the data buffer flags containing actual data in the same file, then taking those offsets mod 16384 to show where the offsets cross block boundaries, we can see that the indices of the records at the end of each block correspond to the aforementioned values:

	Offset to Data Buffer Flag	
Index	(aka "Record Control Word")	Offset mod 16384
1	16412	28
2	17743	1359
3	18190	1806
	:	
33	31600	15216
34	32047	15663
(35	32494	16110
36	32941	173
37	33388	620
38	33835	1067
	<u>:</u>	
70	48139	15371
71	48586	15818
(72	49033	16265)
73	49480	328
74	49927	775
75	50374	1222
	<u>:</u>	
106	64231	15079
107	64678	15526
(108	65125	15973
109	65572	36
110	66019	483
111	66466	930

## 3.7 Data Buffer Flags

The Data Buffer Flags are interspersed within actual file data and bookend the start and end of each file. The first Data Buffer Flag in a TBM archive is located at the beginning of the second TLIB/bk block. All successive Data Buffer Flags can be found by moving forward in the file by the amount specified in each nextPtrOffset. The Data Buffer Flags are also referred to as the "record control word" or the "data buffer field."

Record start EOD EOD Load point lead point lear. follows EOL Parity error c. not written Rec. short	0 49 48 47 46 45 No. bits. in last dataword	44 43 42 41 40 Mode of data	39 38 37 36 35 34 33 32 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 11 13 12 11 10 9 8 7 6 5 4 3 2 1 0    Words to previous pointer   Words to next pointer
Lab			

Length	Bits	Type	API	Description
1	59	Binary	isRecordStart	Start of record
1	58	Binary	isEOD	End of data in this volume
1	57	Binary	isEOF	End of file
1	56	Binary	isLoadPoint	Load point for tape simulation
1	55	Binary	${\tt labelRecordFollows}$	Label record follows
1	54	Binary	endLabelGroup	End of label group file mark
1	53	Binary	${ t source} { t Record Has Parity Error}$	Source record had a parity error
1	52	Binary	${\tt recordNotWritten}$	Record not written (direct access volume)
1	51	Binary	recordIsShorter	Record shorter than words to next pointer-1, length is in bits 0-21 of first data word
6	50–45	Binary	numBits	Number of bits in last data word controlled by this pointer
5	44–40	Binary	recordDataMode	Mode of data in this record (see Data Type bits 51–44 of first word of SYSLBN)
19	39-21	Binary	prevPtrOffset	Words to previous buffer pointer
21	20–0	Binary	nextPtrOffset	Words to next buffer pointer

## 3.8 First End-Of-File Label (EOF1)

All of the characters in EOF1 correspond directly to those in HDR1, but only characters 5–54 and 61–80 of EOF1 will have the (exact) same values as those of HDR1 in a given file; characters 55-60 contain the block count, which changes between HDR1 and EOF1. Characters 1–4 change from HDR1 to EOF1, so only the first word (word 0) of EOF1 is shown. For comparison, consider the HDR1 and EOF1 at the offsets shown in the table below from the CODE-II file G51452:

Field	HDR1 Value	EOF1 Value
Offset <sup>2</sup>	16394	5050071
hdr1/eof1	"HDR1" (0x20449C)	"E0F1" (0x14F19C)
dataSetID	"NCARSYSTEMHD10001"	"NCARSYSTEMHD10001"
volSerialName2	"G51452"	"G51452"
fileSecNum	"0001"	"0001"
${ t file Seq Num}$	"0001"	"0001"
${\tt generationNum}$	"0001"	"0001"
${\tt versionNum}$	"00"	"00"
${\tt creationDate}$	" 82320"	" 82320"
expDate	" 83320"	" 83320"
accChar	" " (0x2D)	" " (0x2D)
blockCount	"000000"	"011259")
sysCode	"NCAR SYSTEM"	"NCAR SYSTEM"

Observe that the block count changes from 0 to 11259; in this file, there are 11259 records between HDR1 and EOF1.

#### 3.8.1 EOF1 Word 0

Ler	igth	Bits	Туре	API	Description
	18	59–42	DPC		The string "E0F1".
	42	41-0	DPC		Same as in HDR1.

offset   nex	t FCP   num	ber   offs	• •	disposition   t	уре	is   is   is   obsolete?   EOF?
						0   0

<sup>&</sup>lt;sup>2</sup>"Offset" here is not a field in HDR1 or EOF1, but rather the offset in the file to the start of each of these sequences.

400	10	339	8486   0	0   0	0   0	- 1
410	0	0	0   0	0   0	0   1
